

ABSTRACT OF DISCLOSURE

This invention is an engine that uses the power of the repelling force of natural magnets to create a turning energy. This turning energy is produced by a system of conveyer belts, pulley rings, and gears that are connected to a "magnetic hammer" piece to react at the right time to allow the "magnetic hammer" piece to go up and repel the magnet on an arm and the other hammer piece proceeding the arm to go down and out of the way for the arm to pass. This arm will be connected to a middle bar that will be connected to the system just stated and be the object that turns to which can be used for anything that needs a turning energy. This invention will be an alternative to engines that run on other more expensive or time costly power sources.
